

# The ROOT framework

done by other software run in physics:

- Event generation and detector simulation
  - Data Acquisition
  - Data Storage
  - Data Analysis
- It permits an easy management of large-scale experiments with many subsystems involved.

# Utilities / Services of ROOT

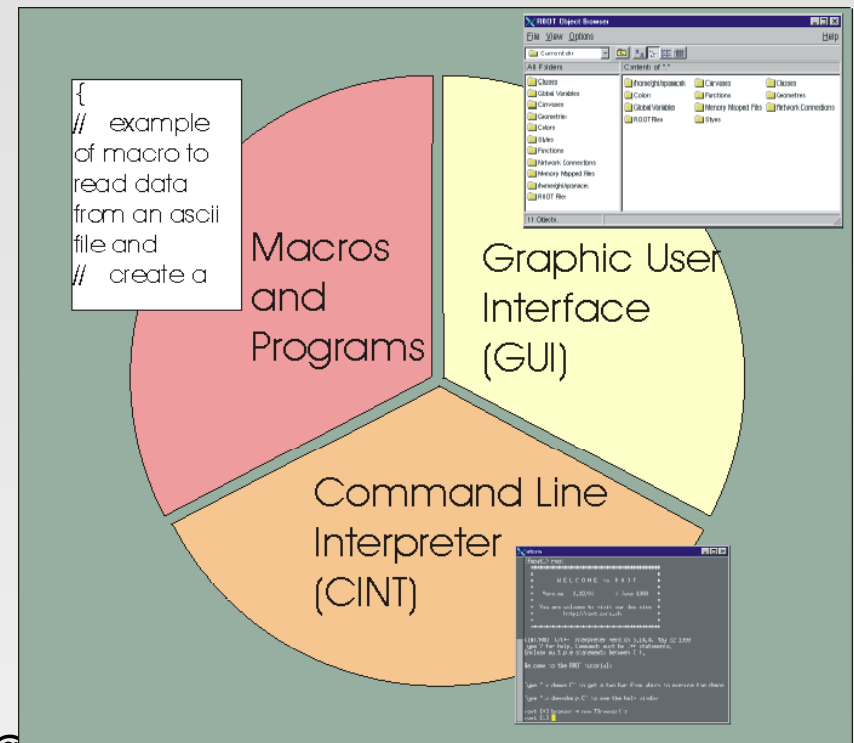

- Using low-level C++ calls ROOT can retrieve data stored on memory or sent by the DAQ.
- **Save Data**
  - ROOT provides a data structure (called tree) that is extremely powerful for fast access of huge amounts of data much faster than accessing a normal file
- **Access Data**
  - ROOT trees spread over several files can be chained and accessed as a unique object, allowing for loops over huge amounts of data.

# Utilities / Services of ROOT

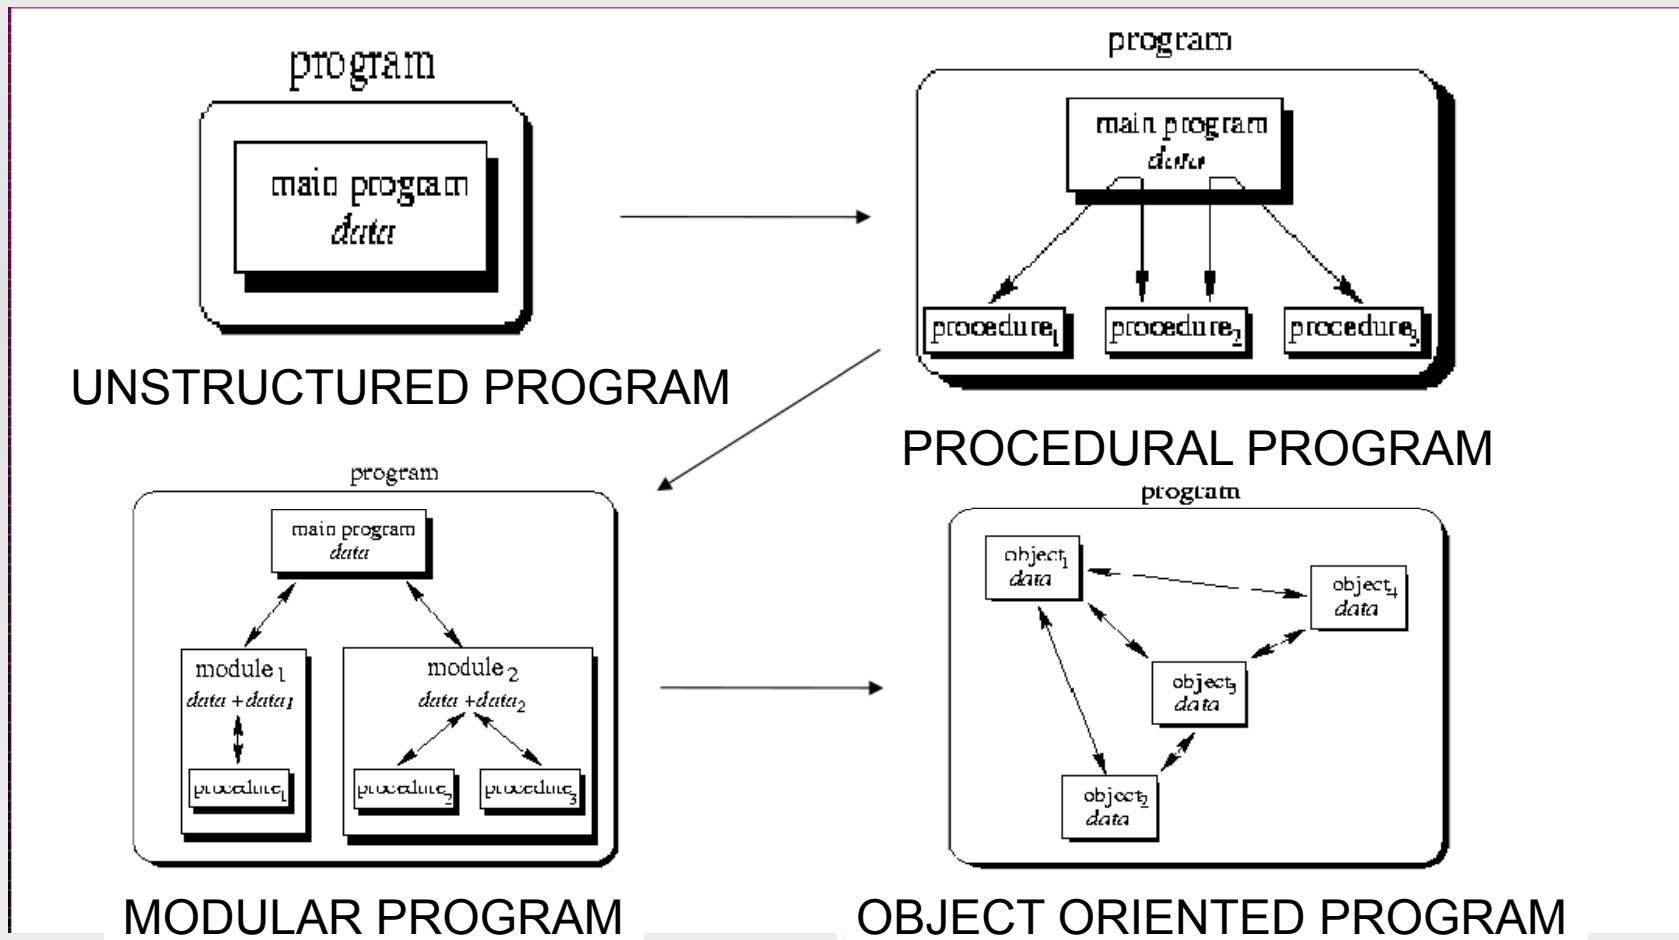

- **Process Data**
  - ROOT has powerful mathematical and statistical tools are provided to operate on your data. Fitting and random number generation are its strongpoints.
- **Show Results**
  - Publication-quality histograms, scatter plots, fitting functions, etc. may be shown and adjusted real-time.

# 3 ways of using ROOT

- ROOT can be coded interactively:
  - Just like a command-line interpreter, e.g. Bash. This mode uses the CINT syntax.
  - You can write macros that are interpreted by CINT
- ROOT programs can be compiled in for better performance.

# Architecture

# Terminology in OO program

- Example: **TH1F** is the class defining a ROOT 1-D histogram with floating-point (32 bits) values.
- **Object:** the instance of a class
  - To define an histogram, one declares it as TH1F hist;
- **Method:** a function of the class
  - Example: hist.Draw() calls the function that draws.
- **Member:** data structure stored in the class
- **Inheritance:** the class "is the daughter" of another, and inherits some of its mother's members

# Resources for self-help

simple arrays to spectrum analyzers. Knowing all of them by heart is not easy.

- Extensive additional documentation is provided in the website:
  - User's Guide
  - Tutorials
  - HowTo's
  - FAQ's

# First steps into ROOT

- \$ROOTSYS is set and so are \$PATH and \$LD\_LIBRARY\_PATH
- Typing "root" at the shell will get you to:
  - **root [0]**
- Welcome to the CINT, the ROOT C++ interpreter!
  - It is not a compiler, executes commands right away
  - It has auto-completion features and other amenities
  - It is less stable than you'd like it to be :(

# Hello World 1 / 4

- `root [0] cout << "Hello World!" << endl;`  
`Hello World!`
- `cout` and `<<` are the commands in the standard C++ namespace for printing out to std output.
- Hello world example 1.1 – `char[]` variable
  - `root [1] char hwrlid_c[12] = "Hello World!"`
  - `root [2] cout << hwrlid_c << endl;`  
`Hello World!`
- Here we declared an array of 12 chars, initializing it to "Hello World!", and printed it.

# Hello World 2 / 4

- `root [3] TString hwrd_s = "Hello World!";`
- `root [4] cout << hwrd_s << endl;`  
`Hello World!`
- `root [5] Int_t len = hwrd_s.Length();`
- `root [6] cout << len << endl;`  
`12`
- Here we used the built-in ROOT TString class. As you can see the **instance** of the TString is called `hwrd_s`, and one of its **methods** is `Length()`, which returns an integer.

# Hello World 3 / 4

- `root [10] TPaveLabel hwrl_d_p( →  
TPaveLabel TPaveLabel()  
TPaveLabel TPaveLabel(Double_t x1, Double_t y1, Double_t  
x2, Double_t y2, const char* label, Option_t* option = "br")  
TPaveLabel TPaveLabel(const TPaveLabel& pavelabel)`
- `root [11] TPaveLabel hwrl_d_p( 0.3,0.3,0.7,0.7,"Hello  
World!","brNDC")`
- `root [12] hwrl_d_p.Draw();`

# Hello World 3 / 4

- In this last example, we first declared an instance to the class `TPaveLabel`
- With the command (...) we constructed it
- As before, the methods of this instance are called with "."
- Since this is a graphical class, CINT has automatically spawned a **TCanvas** where to draw.
- You can play with your mouse over it now and change it.

# Hello World 4 / 4 : the macro

- **myMacro.cxx**

```
void myMacro(){  
    cout << "Hello World!" << endl;  
}
```

- Then, you can run it from inside CINT:

- **root [14].x myMacro.cxx**

- Or directly from the shell:

- **\$ root -q -b myMacro.cxx**

- Will give you the ability of reviewing your work as you go. -q and -b mean "quiet" and "batch".

# Hello World 4 / 4 : the macro

- **myMacro2.cxx**

```
Int_t myMacro2(Int_t k=0){  
    cout << "The input is " << k << endl;  
    return k;  
}
```

```
Double_t anotherFunc(Int_t j=0){  
    Double_t pp = 2*TMath::ACos(-1);  
    Double_t x = 1.5*j + pp*myMacro2(j);  
    return x;  
}
```

- To be able to use anotherFunc, **load** the macro,

- **root [] .L myMacro.cxx**

G.Giavitto - ROOT tutorial @ ScInEGHE

# Variable Types in ROOT

- Basic types: capitalised and have suffix “\_t”:  
`int` → `Int_t` `float` → `Float_t` `double` → `Double_t`
- Names of classes start with “T”:  
`TH1F`, `TF1`, `TString`, `TDirectory`, `TFile`, `TTree`...
- Some ROOT types (classes):
  - `TH1F` - Histogram, containing `Float_t` objects (floats)
  - `TString` – String container
  - `TF1` – 1-dimensional function, `TF2`, ...
  - `TTree` – can store per-event info
- see <http://root.cern.ch/root/html/ListOfTypes.html>

# C++ operations within ROOT

- `root [0] Int_t a;`  
`root [1] a = 5.1;`  
`root [2] cout << "a = " << a << endl;`  
`a = 5`  
`root [3] Double_t b;`  
`root [4] b = 5.1;`  
`root [5] cout << "b = " << b << endl;`  
`b = 5.1`
- Loops and controls: e.g. for loop with if/else
  - `for (Int_t i=1; i < 10 ; i++ ) {`  
`if (i%2 == 0 ) cout << i << " is even" << endl;`  
`else cout << i << " is odd" << endl;`  
`}`

# C++ operations within ROOT

- `root [] Int_t billy[5] = { 16, 2, 77, 40, 12071 };`

- `root [] Int_t jimmy[3][5];`

- Pointers and dynamic memory:

- `root [] Float_t *bobby; // this is a pointer`  
`root [] Int_t narr = 100;`  
`root [] bobby = new Float_t [narr];`  
`bobby`  
`(Float_t*)0x8f1a4c8`

# C++ resources

”course”:

[www.cplusplus.com](http://www.cplusplus.com)

- C++ for ROOT users, from FNAL:  
<http://www-root.fnal.gov/root/CPlusPlus/>
- Standard template library (advanced stuff):  
<http://www.sgi.com/tech/stl/>

# Functions: TMath and TF1

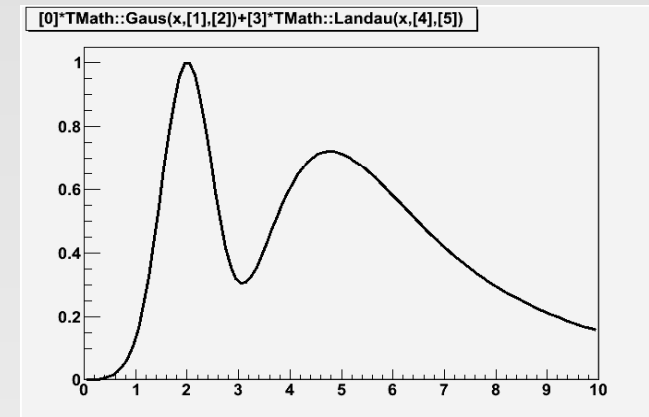

TMath class. You can call them directly:

- `root [] TMath::TanH(1)`  
`(Double_t)7.61594155955764851e-01`

- You can also define your own functions, using TF1:

- `root [] TF1 *f(`  
`= new TF1("test_f",`  
`"[0]*TMath::Gaus(x,[1],[2]) +`  
`[3]*TMath::Landau(x,[4],[5])"`  
`0.0,10.0);`

- `root [] f->SetParameters(1.0,2,0.5,4,5,1);`  
`root [] f->Draw()`

# More math niceties

TRandom class and its daughters:

- `root [] TRandom3 rnd;`  
`root [] rnd.SetSeed(123456);`  
`root [] rnd.Poisson(3.4)`  
`(Int_t)2`  
`root [] f->GetRandom(0.0,10.0)`  
`(Double_t)2.08103799934920897e+00`
- Physics vectors used to represent spacetime vectors and their transformations:
  - `root [] TVector3 r(1,0,0);`  
`root [] r.Rotate(TMath::Pi()/6.0,TVector3(0,1,0));`  
`root [] cout << r.Z() << endl;`  
`-0.5`  
`root [] TLorentzVector rl(r,1.0)`

# Histograms: TH1

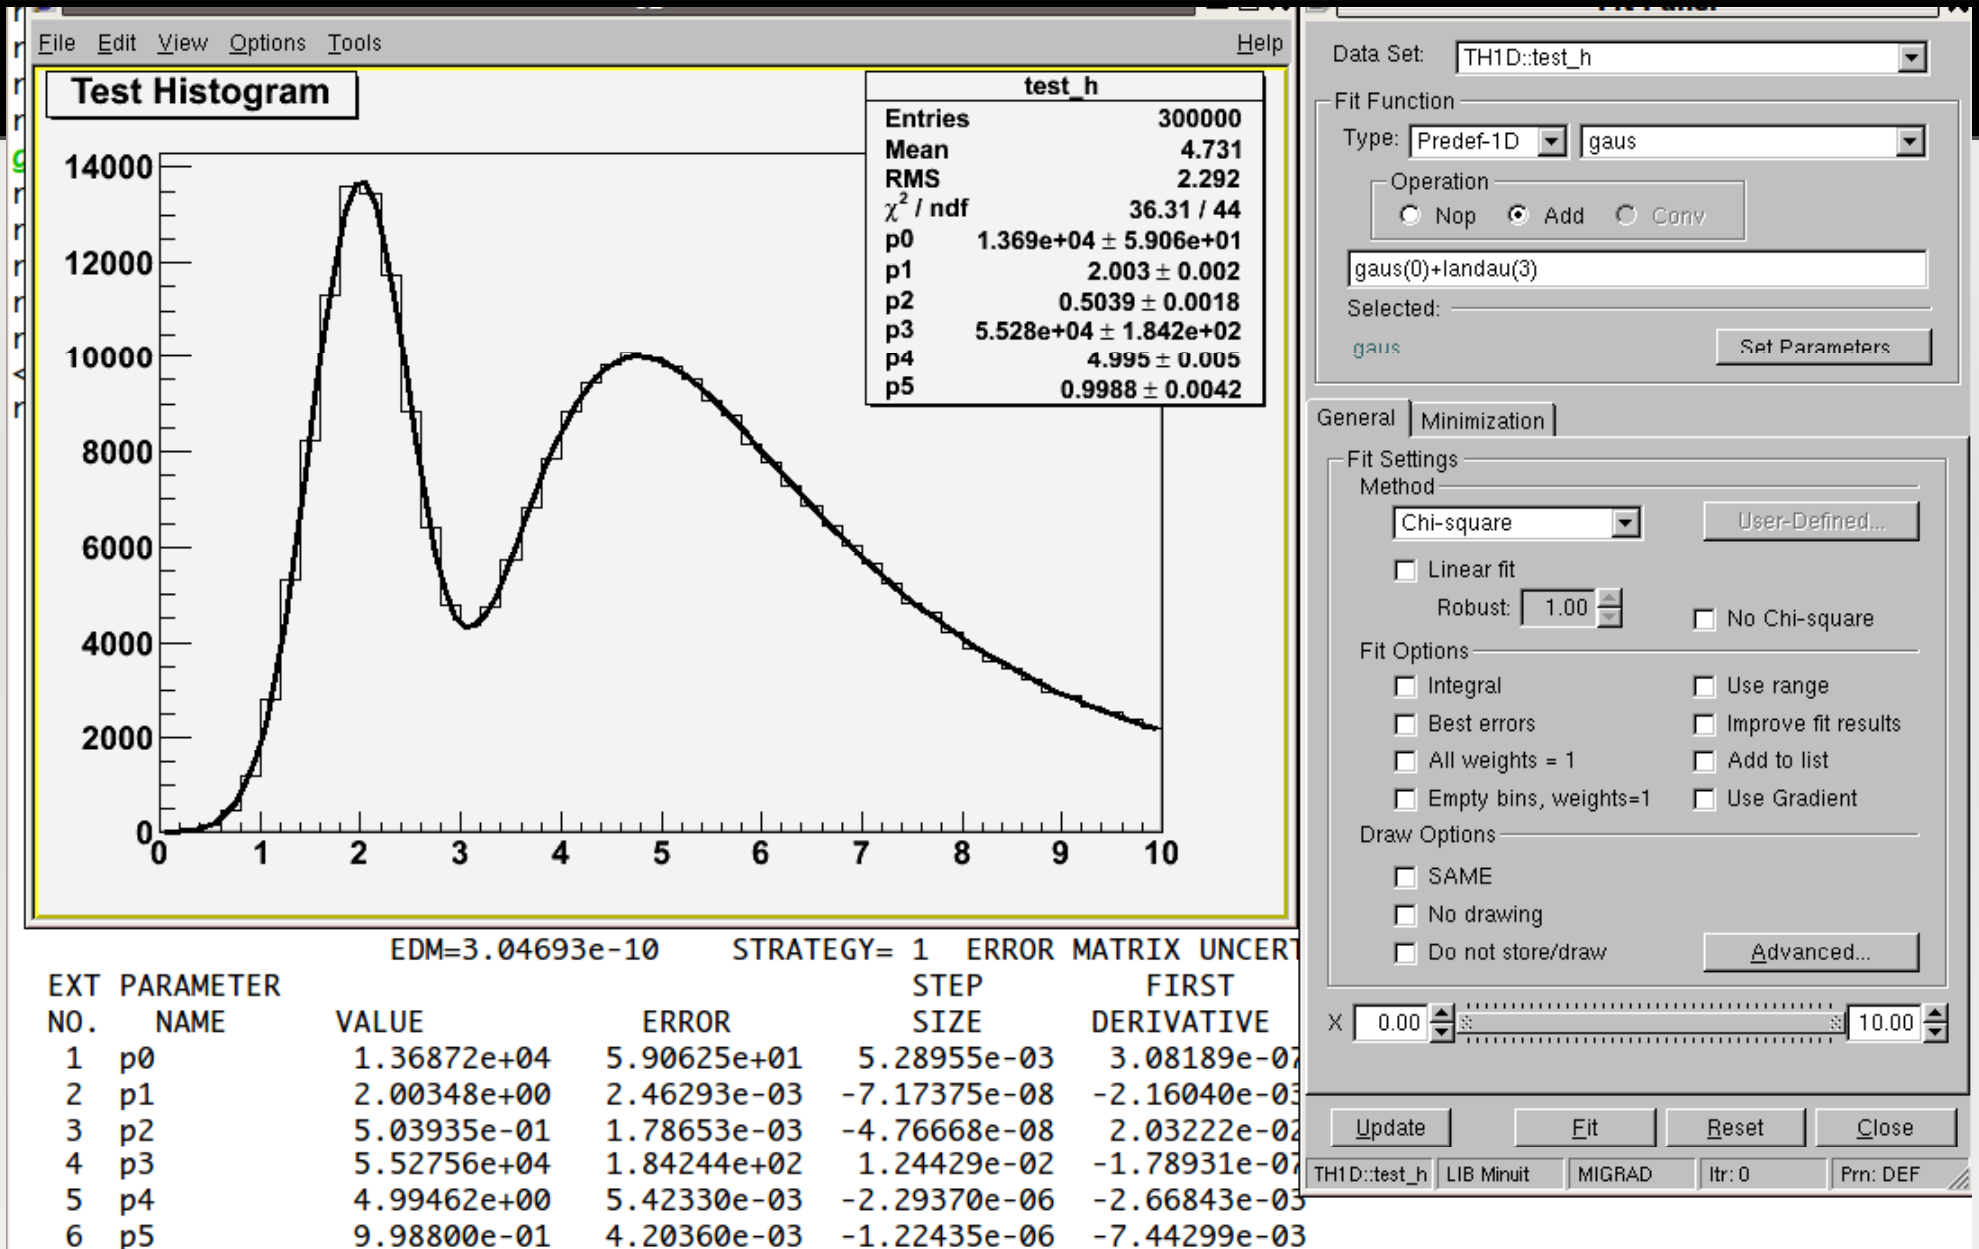

- Permit to organize 1D data in bins, or channels.
  - **TH1::Fill(val)** fills the histogram with an entry
  - **TH1::SetBinContent(bin,val)** sets the bin content
- It also stores the expected error for each bin.
  - **TH1D \*h = new TH1D("hist", "Histo", 50, 0, 10);**
  - **for (Int\_t i=0; i<1e6 ; i++){**  
**h->Fill(f->GetRandom(0,10));**  
**}**
  - **h->FillRandom("test\_f", 1e6); // equivalent**
- Then we can display it, and fit it as well!
  - **h->Draw()**

# Fitting histograms

distribution. The method is `Fit()`.

- `TFitResultPtr fres1 =`  
`h->Fit("gaus","S","",0,3);`  
`TFitResultPtr fres2 =`  
`h->Fit("landau","S","",3,10);`  
`Double_t pars[6];`  
`for (Int_t i =0;i<3;i++) {`  
    `pars[i] = fres1.Get()->GetParams()[i];`  
    `pars[i+3] = fres2.Get()->GetParams()[i];`  
`}`  
`TF1 *f2 = new TF1("fit_f","gaus(0) + landau(3)",0,10);`  
`f2->SetParameters(pars);`  
`h->Fit(f2,"", "",0,10);`

# Fitting an Histogram: GUI

# Scatter plots

- `Int_t n = 20;`  
`Double_t x[n], y[n]; // this works only in CINT!!!`  
`for (Int_t i=0; i<n; i++) {`  
`x[i] = i*0.1;`  
`y[i] = 10*TMath::Sin(x[i]+0.2);`  
`}`  
`TGraph *gr1 = new TGraph (n, x, y);`
- We can draw the graph with these options
  - `gr1->Draw("APL")`  
`gr1->SetMarkerStyle(20);`  
`gr1->Draw("APL");`
- And also fit it with a polinomial !
  - `gr1->Fit("pol1", "", "", 0.1, 1.0);`  
`gr1->Fit("pol2", "", "", 0.1, 2.0);`

# Canvases and Pads

- Single TCanvas w/ multiple TPad's with TCanvas::Divide

```
root [] TCanvas c1("c1", "First canvas", 400, 300);
root [] c1.Divide(2, 3);
root [] c1.cd(4);
root [] TLatex l(0.1, 0.4, "#int_{K} f(z) dz = 0");
root [] l.SetTextSize(0.25);
root [] l.Draw();
```

- The objects here are put on the **stack**, the part of volatile mem. that is discarded when a function returns. Does not work in macro.

- Use dynamic memory allocation: **operator new** and **to call Members**

# ROOT Files : TFile

and sub-folders.

- It can be opened Read-only (default), for writing (NEW), adding (UPDATE), rewriting (RECREATE):
  - `root [] TFile f0("file0.root", "MODE");`
- Once opened it becomes the current directory.
- Any ROOT class object deriving from TObject can be written on the file using TObject::Write(), or Append();
- When the file is closed the contained objects are no longer available to ROOT.
- To see what is in a file TFile::GetListOfKeys()::Print()
- To retrieve an object from a File, TFile::Get(obj\_name)

G.Giavitto - ROOT tutorial @ ScinEGHE

# Data Structures in ROOT

rows="EVENTS", columns = "DATA VARIABLES"

- ROOT implements this paradigm within a more powerful interface: the **TTree**.
- Its structure is similar to that of a filesystem: it is **branched**, analogously to having directories and sub-directories, containing files (**leaves**).

G.Giavitto - ROOT tutorial @ ScInEGHE

'10

# TTrees in more detail

simpler trees (**TNtuple**) have branches of single variables, reproducing the table paradigm.

- A branch may contain:
  - **simple variables**;
  - objects inheriting from **TObject**;
  - objects of the **TClonesArray** class (a collection of objects of the same class);
  - a **STL container** of pointers to objects.
- If it is needed a TTree can be saved on different files, and retrieved in full using one of its derivative classes: **TChain**

# A very simple Tree

```
      x           y           z
-0.676641 0.390352 0.610218
```

...

- The implementation is easy:
  - `root[] TTree *T = new TTree("ntuple","ascii data");`  
`root[] T->ReadFile("basic.dat","x:y:z");`
- We can already draw 2-D histograms with cuts:
  - `root [] T->Draw("x:y","z>2","lego");`
- And save the Tree:
  - `root [] TFile *f = new TFile("basic.root","NEW");`  
`root [] T->Write();`

# A simple Tree

- ```
root [] Float_t x,y,z;  
root [] TTree *T2 = new TTree("ntuple2","ascii2");  
root [] T2->Branch("x_pos",&x,"x/F")  
root [] T2->Branch("y_pos",&y,"y/F")  
root [] T2->Branch("z_pos",&z,"z/F")
```
- Then we fill it:
  - ```
root [] ifstream in("basic.dat");  
root [] while (1) {  
in >> x >> y >> z;  
if (!in.good()) break;  
T2->Fill(); }
```
- And save it:
  - ```
root [] T2->Write();  
root [] f->Close();
```

# Reading a TTree from a TFile

- `root [] TFile f("basic.root");`  
`root [] .ls`

```
TFile**          basic.root
TFile*          basic.root
KEY: TTree ntuple;1      ascii data
KEY: TTree ntuple2;1    ascii data
```

- Then create a pointer to the Tree:
  - `root [] TTree *Tr = (TTree*)f.Get("ntuple");`  
`root [] Tr->GetListOfBranches().Print();`

```
Collection name='TObjArray', class='TObjArray', size=16
*Br  0 :x      : x/F      *
*Entries : 1000 : Total Size= 4528 bytes File Size = 3824 *
*Baskets : 1 : Basket Size= 32000 bytes Compression= 1.06 *
* .....*
```

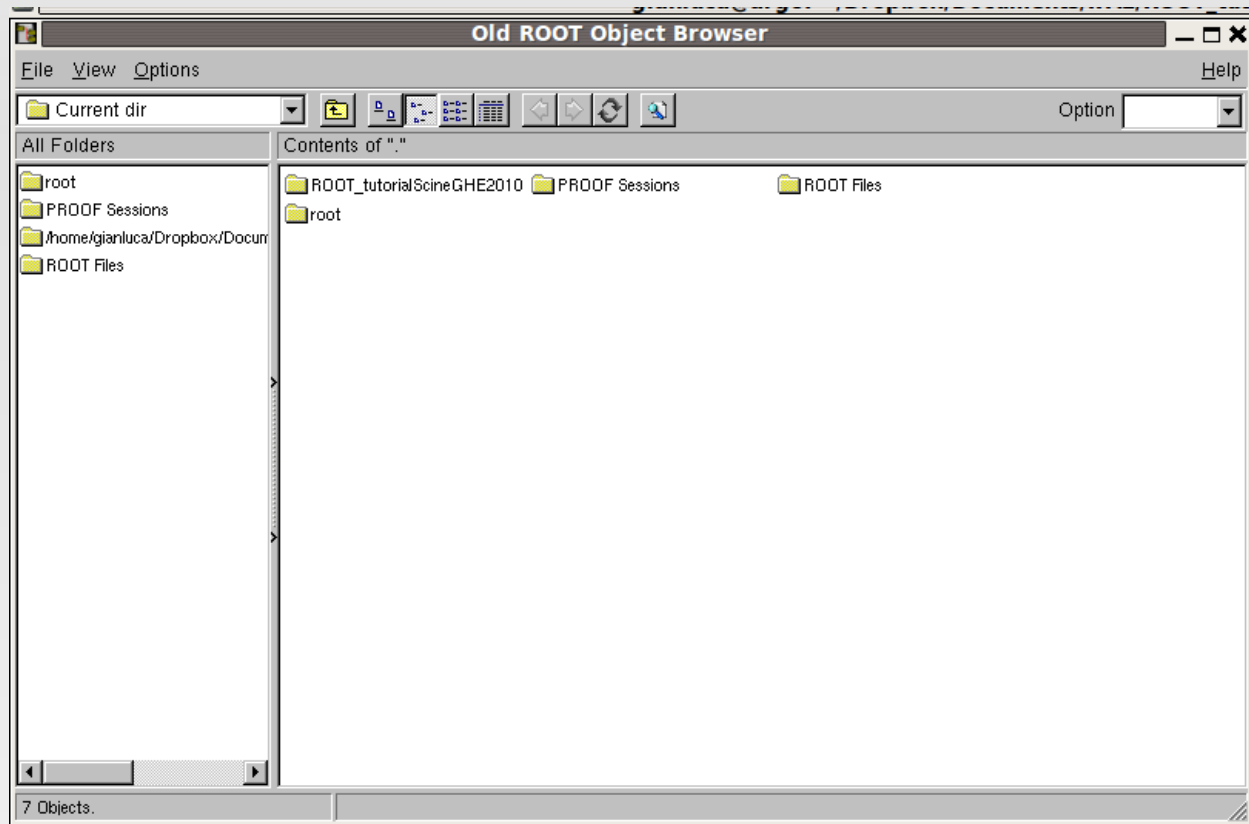

# Reading a TTree from a TFile

- `root [] Float_t x,y,z;`  
`root [] Tr->SetBranchAddresses("x",&x);`  
`root [] Tr->SetBranchAddresses("y",&y);`  
`root [] Tr->SetBranchAddresses("z",&z);`
- We can then loop over the entries and get them:
  - `root [] TH2D *hz =`  
`new TH2D("x:y", "x vs. y", 40, -5, 5, 40, -5, 5)`  
`root [] Int_t ne = Tr->GetEntries();`  
`root [] for (Int_t i=0; i<ne; i++) {`  
    `Tr->GetEntry();`  
    `if (z > 2) hz->Fill(x,y);}`  
`root [] hz->Draw("lego");`

# Graphical relief

Let's have a look to what we've done:

- `root [] TBrowser *b = new TBrowser();`

G.Giavitto - ROOT tutorial @ ScInEGHE

# Graphical relief II

Go to the TTree , Right Click, Start Viewer.

The screenshot displays the ROOT software interface. On the left, the 'TTree viewer' window shows a tree structure with columns for variables x, y, and z. The 'Current Tree' is named 'ntuple'. Below the tree list, there are buttons for 'SPIDER', 'STOP', and a refresh icon. At the bottom of the viewer, a message reads: "You are using the old ROOT browser! A new Select the 'New Browser' entry from the ' 'Browser.Name:' from 'TRootBrowserLite' to".

On the right, a window titled 'c1' displays a 3D histogram plot. The plot shows a distribution of data points in a 3D space with axes labeled x, y, and z. The x-axis ranges from -5 to 3, the y-axis from -2 to 2, and the z-axis from 0 to 12. The histogram bars are white with black outlines, and the plot is rendered in a perspective view.

# Using a class to fill a TTree

down exactly to our analysis needs.

- First we need to **declare** the class:

- **file class\_tree.C:**

```
class TrackPoint : public TObject {  
  public:  
    Float_t x,y,z;  
    TrackPoint() { x=0;y=0;z=0;}  
    ClassDef(TrackPoint,1)  
};
```

- Then we can write the function body, which is much like what we did before.

# The macro body

```
ClassImp(TrackPoint)
void class_tree()
{
  TFile *f = new TFile("data.root","NEW");
  TTree *T = new TTree("points","ascii");
  TrackPoint *tp = new TrackPoint();
  T->Branch("tp",&tp);
  ifstream in("basic.dat");
  while (1) {
    in >> tp->x >> tp->y >> tp->z ;
    if (!in.good()) break;
    T->Fill();
  }
  T->Write();
  f->Close();
}
```

- class defin.
- TFile and TTree
- Declare class
- Branch Tree
- Read in values
- Fill Tree
- Write and Close

# Running as compiled-in

declared a class derived from a compiled one, it is necessary to run the macro as compiled code.

- This will produce a lot of errors because we did not include the proper libraries. (Interpreted CINT has that done automatically)

• To solve this problem, add to the top of `class_tree.C`:

```
#include "TROOT.h"  
#include "TFile.h"  
#include "TTree.h"  
#include <iostream>  
#include <fstream>
```

```
using namespace std;
```

• Then run it with:

```
root[] .x class_tree.C+
```

# Reading the Tree (again?)

It is sufficient to replace e.g. `x` with `tp.x` :

- `root [] TFile f("data.root")`

Warning in <TClass::TClass>: no dictionary for class TrackPoint is available

```
root [] TTree *Tr = (TTree*)f.Get("points")
```

```
root [] Tr->Draw("tp.x:tp.y", "tp.z>2", "lego")
```

```
root [] Tr->Draw("tp.x:tp.y", "tp.z>2", "box")
```

- It is also possible to copy the class definition onto another script and analyze the data.
- What if you don't have info on how the Tree was created, which classes were declared?

# The TSelector framework

It is able to recreate the classes it was created with:

- `root [] Tr->MakeSelector()`  
Info in `<TTreePlayer::MakeClass>`: Files: `points.h` and `points.C` generated from TTree: `points`
- The two files generated must now be modified to fit our needs. A detailed walkthrough is found on <http://root.cern.ch/drupal/content/accessing-ttree-tselector>
- `root [] Tr->Process("points.C"); //or`  
`root [] Tr->Process("points.C+");`
- This harnesses the full power of ROOT.

# Hands – On session: goals

- Review the examples
- Learn how to use well the documentation provided at [root.cern.ch](http://root.cern.ch) and elsewhere.
- Read into a TTree the data produced by the previous Geant 4 simulation.  
(Probably will need `$ROOTSYS/tutorials/tree*.C`)
- Quick-check the TTree with GUI.
- From it, construct an analysis environment with TSelector, and run it.
